[Title of the Invention] IMAGE ENCODER AND IMAGE DECODER

[Claims]

[Claim 1]

An image coding device comprising:

a tile decomposition portion for decomposing image data into tiles each having N pixels \times M pixels and outputting the N pixels \times M pixels in the tile as an objective data to be coded for a corresponding each of the tile;

a wavelet coding portion for extrapolating a predetermined data at the periphery of the objective data from the tile decomposition portion, decomposing each of the tiles into subbands and separately wavelet-encoding each of the tiles;

a management information generating portion for generating management information necessary for independently decoding coded data of the subbands from the wavelet coding portion on a tile-by-tile basis as well as on the subband-by-subband basis; and

a coded data integrating portion for combining the data separately wavelet-encoded on a tile-by-tile basis according to the management information outputted from the management information generating portion and attaching the management information to the coded data.

[Claim 2]

An image coding device as defined in claim 1, wherein the tile decomposition portion decomposes original image data into

tiles each of the N pixels x M pixels and outputting, as the objective data to be coded corresponding to said each of the tiles, a result of multiplying each of the tiles and neighboring pixel data by a predetermined two-dimensional window function.

[Claim 3]

An image coding device comprising:

a tile decomposition portion for decomposing image data into tiles each of N pixels x M pixels and outputting the N pixels x M pixels in the tile as an objective data to be coded for a corresponding each of the tiles;

an adjacent pixel adding portion for providing an objective tile to be coded with peripheral pixels necessary for wavelet transformation of the objective tile to be coded when such pixels exist at the periphery thereof;

a wavelet coding portion for extrapolating a predetermined data when no pixel existing at the periphery of the objective tile to be coded, decomposing each of the tiles into subbands and outputting only wavelet coefficients of the codable objective tile;

a management information generating portion for generating management information necessary for independently decoding coded data outputted from the wavelet coding portion on a tile-by-tile basis as well as on a subband-by-subband basis; and

a coded data integrating portion for combining the data separately wavelet-encoded on a tile-by-tile basis according

to the management information outputted from the management information generating portion and attaching the management information to the coded data.

[Claim 4]

An image coding device as defined in claim 3, wherein the each adjacent pixel to be attached to the objective tile is multiplied by a weighting function according to a distance from the objective tile, when each of the objective tiles is attached the adjacent pixel according portion.

[Claim 5]

An image coding device comprising:

a wavelet coding portion for decomposing an image into subbands by extrapolating a predetermined data at the periphery of the image, and performing wavelet encoding of the subbands;

a tile composing portion for reconstructing, from wavelet coefficients inputted from the wavelet coding portion, separate tiles each being composed of $N \times M$ wavelet coefficients forming a (membership) set to be separately entropy coded;

a management information generating portion for generating management information necessary for independently decoding coded data outputted from the wavelet coding portion on a tile-by-tile basis as well as on a subband-by-subband basis; and

a coded data integrating portion for composing a sequence of the coded data according to the management information from the management information generating portion and attaching

the management information to the coded data.

[Claim 6]

An image coding device as defined in any of claims 1 to 4, wherein the wavelet coding portion is provided with a memory necessary for storing at least data for the tile.

[Claim 7]

An image coding device as defined in any of claims 1 to 6, wherein the wavelet-coding portion performs multiple times the subband decomposition process by selectively applying suitable filters for respective subbands.

[Claim 8]

An image coding device having a combination of plural coding systems selectable from claims 1 to 7 and having a plurality of selectively applicable coding modes, which further includes a flag generating portion for generating flags indicating respective coding modes, a control portion for controlling the coding device in a mode specified by the flag generated by the flag generating portion, and a management information generating portion for generating management information from the flags outputted by the flag generating portion and tile-and-subband information.

[Claim 9]

An image coding device as defined in any of claims 1 to 8, which is further provided with an ID generating portion for generating IDs for identifying respective tiles and a management information preparing portion for preparing

management information from IDs generated by the ID generating portion and tile-and-subband information outputted by the wavelet-coding portion.

[Claim 10]

An image coding device as defined in claim 9, which is further provided with a peripheral tile ID deciding portion for generating IDs of adjacent tiles around an objective tile to be coded by using ID information from the ID generating portion and tile information from the wavelet coding portion, and a management information preparing portion for preparing management information from IDs of an ID of the objective tile, IDs of adjacent tiles and tile-and-subband information from the wavelet coding portion.

[Claim 11]

An image decoding device for receiving coded data coded and inputted by the image coding device of claim 1 and reproducing a desired image by selectively decoding the coded data of necessary tiles and subbands, comprising:

a management information separating portion for separating tile-and-subband management information from input coded data;

a coded data extracting portion for selectively extracting coded data of required decodable objective tiles and subbands according to the management information;

a wavelet decoding portion for performing wavelet decoding of the extracted coded data in compliance with the wavelet

coding conducted by the image coding device of claim 1; and
a tile combining portion for combining wavelet-decoded
tile images into a desirable image.

[Claim 12]

An image decoding device for receiving coded data coded
and transmitted by the image coding device of claim 2 and
reproducing a desired image by selectively decoding the coded
data of necessary tiles and subbands, comprising:

a management information separating portion for separating
tile-and subband management information from the input coded
data;

a coded data extracting portion for extracting coded data
part corresponding to an objective tile and subbands according
to the management information;

a wavelet decoding portion for performing wavelet decoding
of the extracted coded data in compliance with the wavelet
coding conducted by the image coding device of claim 2; and

a tile integrating portion for arranging wavelet decoded
data at respective places on an original image and superposing
image values at overlaps of neighboring tiles to integrate the
tiles into a desired decoded image.

[Claim 13]

An image decoding device for receiving coded data coded
and inputted by the image coding device defined in any of claims
3 to 5 and reproducing a desired image by decoding the coded
data of necessary tiles and subbands, comprising:

a management information separating portion for separating tile-and subband management information from the input coded data;

a coded data extracting portion for extracting coded data part corresponding to an objective tile and subbands according to the management information;

a wavelet decoding portion for performing wavelet decoding of the extracted coded data in compliance with the wavelet coding conducted by the image coding device defined in any of claims 3 to 5; and

a tile integrating portion for arranging wavelet-decoded data at respective places on an original image and superposing image values at overlaps of neighboring tables to integrate the tiles into a desired decoded image.

[Claim 14]

An image decoding device for receiving coded data coded and inputted by the image coding device defined in any of claims 3 to 5 and reproducing a desired image by selectively decoding the coded data of necessary tiles and subbands, comprising:

a management information separating portion for separating tile-and subband management information from input coded data;

a coded data extracting portion for selectively extracting coded data of required decodable objective tiles and subbands according to the management information;

a wavelet decoding portion for performing wavelet decoding of the extracted coded data in compliance with the wavelet

coding conducted by the image coding device defined in any of claims 3 to 5, and

a wavelet-coefficient rearranging portion for rearranging the wavelet coefficients reconstructed on a tile-by-tile basis by the wavelet decoding portion into an initial order of them before having been tiled.

[Claim 15]

An image decoding device as defined in any of claims 11 to 14, wherein the wavelet decoding portion includes a memory for storing data at least for the tile.

[Claim 16]

An image decoding device as defined in any of claims 11 to 15, wherein the wavelet decoding portion repeats multiple times the subband composition with use of filters changeable for respective subbands.

[Claim 17]

An image decoding device for receiving coded data encoded and inputted by the image coding device defined in claim 8, the device having a combination of plural decoding systems selectable from claims 11 to 16 with plural decoding modes and selectively decoding coded data for necessary tiles and applicable, wherein it is further provided with:

a management information separating portion for separating management information from the input coded data;

a flag extracting portion for extracting from the management information a flag for specifying a decoding mode

used for decoding the coded data; and

a control portion for controlling the decoding device to be activated in a decoding mode corresponding to the extracted flag.

[Claim 18]

An image decoding device as defined in any of claims 11 to 17, which receives coded data encoded and inputted by the image coding device defined in claim 9 and reproduces a desirable image by decoding the coded data on the subband-by-subband basis and on the tile-by-tile basis, wherein it is further provided with an objective tile deciding portion for deciding an ID of a tile to be decoded and a control portion for controlling input data to the wavelet decoding portion according to management information from the management information separating portion so as to decode only decoded data of the tile having the decided ID.

[Claim 19]

An image decoding device as defined in claim 18, which receives coded data encoded and inputted by the image coding device of claim 10 and reproduces a desirable image by selectively decoding the coded data on the subband-by-subband basis and the tile-by-tile basis, wherein it is further provided with a buffer for storing input coded data and a control portion that recognizes next coded data to be decoded being a tile decided by the objective tile decided portion by referring to the management information separated by the

management information separating portion and controls the buffer so that only coded data for the decided tile and adjacent tiles specified by the management information is inputted to the wavelet decoding portion.

[Detailed Description of the Invention]

[0001]

[Technical Field to which the Invention Pertain]

The present invention generally relates to the field of digital image processing and, more specifically, to an image coding device for encoding digital image data with high efficiency and an image decoding device for decoding coded data encoded by the image coding device.

[0002]

[Prior Art]

Flash Pix format specification version 1.0 has been proposed as an image format for converting natural image data into digital data suitable for computer processing.

[0003]

This format specification permits a plurality of data with different resolutions to be stored together therein so that any data suited to an actual display and/or printing device can be selected and taken-out promptly in response to a user's request. Furthermore, each image is divided into tiles arranged in the format that allows the user to select only a necessary data portion of the image and process it in an enlarged or reduced size with a reduced processing load.

[0004]

Referring to Figures 32 an image coding device for encoding an image according to the flash pix format is described as follows. In Fig. 32(a), images are shown in different reduced scales, each of which are divided into tiles. Figure 32(b) is a block diagram of an exemplary image coding device.

[0005]

The flash pix method is featured in that it generates first images 1 to 4 in sizes $1/1$ to $1/8$, as shown in Fig. 1, then divides each image into tiles and compresses data of each tile image.

[0006]

First, a case of encoding an image 1 shown in Fig. 32(a) by the coding device of Fig. 32(b) is described. In Fig. 32(a), a dashed line shows the boundary between tiles.

[0007]

A tile decomposition portion 3201 divides an original image into tiles each comprising 64×64 pixels, which tiles are then compressed one by one by a JPEG compressing portion 3202. In a coded data integrating portion 3203, coded data of each tile is combined with tile decomposition information from the tile decomposition portion 3201 to form coded data 1 to be output.

[0008]

The image 2 of Fig. 32(a) is described. The original image 0 is reduced to $1/2$ in length and width by a $1/2$ contraction portion 3204, and then the $1/2$ -size image is processed through

a tile decomposition portion 3205, a JPEG compressing portion 3206 and a coded-data integration portion 3207 to form coded data 2.

[0009]

Size reduction of the image to generate a group of size-reduced images in Fig 32(a) (Images 2 to 4) is repeatedly performed until a downsized image containable within a single tile is obtained. For example, the image 3 is still larger than a tile and is further contracted by a factor of 2 to obtain the image 4 allowable within a single tile as shown in Fig. 32(a). The size-reduction procedure is now finished.

[0010]

Coded data for the image 3 is produced through a 1/2 contraction portion 3208, a tile decomposition 3209, a JPEG compressing portion 3210 and a coded data integration portion 3211. Coded data for the image 4 is produced through a 1/2 contraction portion 3212, a tile decomposition portion 3213, a JPEG compressing portion 3214 and a coded data integration portion 3215.

[0011]

However, the above-described system involves the following problems: Storing coded data for images downsized with different resolutions in addition to coded data for the image with the scale 1:1 results in increasing a volume of coded data by a factor of 1.4. Furthermore, compression for encoding data must be done for each resolution image, resulting in

considerably increasing processing load.

[0012]

On the other hand, apart from the Flash Pix method, the image compression can be also accomplished by the wavelet transform technique whereby image data with different resolutions can be easily decoded from coded and compressed data of an original-size image. This technique is therefore free from the problem with increasing the amount of coded data.

[0013]

Namely, the wavelet transform method can meet the demand for decoding data with different resolutions without any increase by a factor 1 in volume of coded data whereas the Flash Pix method has an increase by a factor of 1.4 in volume of coded data.

[0014]

Figure 33 is a basic block diagram of a wavelet transform coding portion wherein an original image is converted by a wavelet transform portion 3301 into data for subband divisions, which data is quantized by a quantizing portion 3302 and then entropy encoded by an entropy coding portion 3303 to produce coded data.

[0015]

Figure 34 is a detailed block diagram of the wavelet transform portion 3301 of Fig. 33.

Figure 35 depicts an example of the wavelet transformation of an image. Figures 34 and 35 are shown as an example of

conducting two-dimensional subband decomposition three times.
[0016]

An original image shown in Fig. 35(a) is filtered through a horizontal low-pass filter 3401 and a horizontal high-pass filter 3402 to create two horizontal subbands that are then decimated to 1/2 respectively by 1/2-subsampling portions 3407 and 3408.

[0017]

Two horizontally divided subbands are divided each into two subbands through vertical low-pass filters 3403, 3405 and vertical high-pass filter 3404, 3406, which subbands are decimated each to 1/2 by 1/2 sampling portions 3409 to 3412. Consequently, four subbands are formed.

[0018]

A high-horizontal and high-vertical frequency subband " λ " (Fig. 34), a high-horizontal and low-vertical frequency subband " μ " (Fig. 34) and a low-horizontal and high-vertical frequency subband " ν " (Fig. 34) correspond to wavelet transform coefficients " ν ", " μ " and " λ " (Fig. 35(b)) respectively.

[0019]

After this, only a remaining low-horizontal and low-vertical frequency subband 3413 is recursively divided into subbands.

[0020]

This recursive subband decomposing process is performed by horizontal low-pass filters 3414, 3426, horizontal

high-pass filters 3415, 3427, vertical low-pass filters 3416, 3418, 3428, 3430, vertical high-pass filters 3417, 3419, 3429, 3431 and 1/2-sampling portions 3420-3425, 3432-3437.

[0021]

Sub-bands "1"- "3" (Fig. 34) correspond to sub-bands "1"- "3" (Fig. 35(b)) respectively.

[0022]

Wavelet transform coefficients shown in Fig. 35(b) are quantized on a subband-by-subband basis by a quantizing portion 3302 (Fig. 33) and then entropy encoded by an entropy coding portion 3303 to produce coded data. The entropy-coding portion 3303 may use Huffman coding or arithmetic coding.

[0023]

On the other hand, wavelet-coded data is decoded by an entropy decoding portion 3601 and inversely quantized by an inverse quantizing portion 3602. Subbands are then combined by an inverse wavelet transform portion 3603 to produce a decoded image (Fig. 36).

[0024]

Image-encoding using the wavelet transform technique is featured by hierarchical structure according to resolution levels as shown in Fig. 35(b). This method can easily decode images having different resolution levels from a part of coded data or a whole coded data.

[0025]

Namely, an image of a quarter (1/4) the original image size

can be decoded by decoding subbands "1", "0", "A" and "2" in Fig. 35(b). An image of a half (1/2) the original image size can be decoded by decoded subbands "1", "0", "A", "2", "3", "4" and "5". A complete (1/1) size image can be produced by decoding all subbands.

[0026]

Referring to Fig. 37, the operation of the horizontal low-pass (H-LP), horizontal high-pass (H-HP), vertical low-pass (V-LP) and vertical high-pass (V-HP) filters shown in Fig. 34 will be described as follows. Figure 37(b) is an enlarged view of an encircled part of Fig. 37(a).

[0027]

When an output of a horizontal 9 tap filter, associated with a pixel 3701 positioned right top on the original image is calculated for wavelet transformation of an original image, the operation of the filter must be performed on an area 3702.

[0028]

However, a part of the objective area 3702 is out of the boundary of the original image, where no data exists. The vertical filters may also encounter with a similar problem.

[0029]

Thus, for operation on the periphery of the image, it is often needed to use external data outside the image boundary according to the number of the taps of the filter used. Iteration of the subband decomposition also results in enlarging the area into which the filter extrudes.

[0030]

In general, the above problems are treated in such a manner that the image is folded at its periphery according to a certain given rule.

[0031]

[Problems to be solved by the Invention]

For the Flash Pix method using a plurality of coded data sets separately provided for respective images of different resolution levels, the image processing load such as enlargement or contraction of the image can be reduced, but the data size is increased to 1.4 times.

[0032]

For wavelet-transform coding method, data with different resolution levels can be easily decoded from a single set of compressed and coded data for an original image size and, therefore, no increase in the data size takes place.

[0033]

When the wavelet-transform coding system utilizes the method of decomposing an image into tiles and encoding the image data on a tile-by-tile basis, which is used in the flash-pix system (to reduce the processing load by selectively processing only necessary tiles in case of processing a particular part of the image), however, this arises the above-described problem since filters may stick from the boundary of respective tiles.

[0034]

In other words, the flash pix system using the JPEG coding

can easily perform coding of each tile owing to the closed property of coding in each tile, while the wavelet-transform coding system can not effectively use the above tile-by-tile coding-and-managing method because the processing causes the extrusion of filters out of respective tiles.

[0035]

In addition, the conventional wavelet-transform coding system must have a memory sufficient for storing an output of the wavelet-transform portion 3301 (Fig. 33), i.e., all wavelet transform coefficients as shown in Fig. 35(b). Since these coefficients have the same resolution as that of the original image, the memory has to possess a large capacity. This requirement becomes severer when processing a higher resolution image.

[0036]

In view of the above-described problems of the prior arts, the present invention was made to provide a compact hardware system that realizes effective encoding of images with different resolutions and effective management of coded data by tiles by using an improved wavelet-transform technique.

[0037]

[Means for solving Problem]

An object of the present invention according to the claim 1 is to provide an image coding device comprising:

a tile decomposition portion for decomposing image data into tiles each having N pixels \times M pixels and outputting the

N pixels x M pixels in the tile as an objective data to be coded for a corresponding each of the tile;

a wavelet coding portion for extrapolating a predetermined data at the periphery of the objective data from the tile decomposition portion, decomposing each of the tiles into subbands and separately wavelet-encoding each of the tiles;

a management information generating portion for generating management information necessary for independently decoding coded data of the subbands from the wavelet coding portion on a tile-by-tile basis as well as on the subband-by-subband basis; and

a coded data integrating portion for combining the data separately wavelet-encoded on a tile-by-tile basis according to the management information outputted from the management information generating portion and attaching the management information to the coded data.

[0038]

Another object of the present invention according to the claim 2 is to provide an image coding device having means as defined in claim 1, wherein the tile decomposition portion decomposes original image data into tiles each of the N pixels x M pixels and outputting, as the objective data to be coded corresponding to said each of the tiles, a result of multiplying each of the tiles and neighboring pixel data by a predetermined two-dimensional window function.

[0039]

Another object of the present invention according to the claim 3 is to provide an image coding device comprising:

a tile decomposition portion for decomposing image data into tiles each of N pixels \times M pixels and outputting the N pixels \times M pixels in the tile as an objective data to be coded for a corresponding each of the tiles;

a peripheral pixel adding portion for providing an objective tile to be coded with peripheral pixels necessary for wavelet transformation of the objective tile to be coded when such pixels exist at the periphery thereof;

a wavelet coding portion for extrapolating a predetermined data when no pixel existing at the periphery of the objective tile to be coded, decomposing each of the tiles into subbands and outputting only wavelet coefficients of the objective tile to be coded;

a management information generating portion for generating management information necessary for independently decoding coded data outputted from the wavelet coding portion on a tile-by-tile basis as well as on a subband-by-subband basis; and

a coded data integrating portion for combining the data separately wavelet-encoded on a tile-by-tile basis according to the management information outputted from the management information generating portion and attaching the management information to the coded data.

[0040]

Another object of the present invention according to the claim 4 is to provide an image coding device having means as defined in claim 3, wherein the each peripheral pixel to be attached to the objective tile is multiplied by a weighting function according to a distance from the objective tile, when each of the objective tiles is attached the peripheral pixel according portion.

[0041]

Another object of the present invention according to the claim 5 is to provide an image coding device comprising:

- a wavelet coding portion for decomposing an image into subbands by extrapolating a predetermined data at the periphery of the image, and performing wavelet encoding of the subbands;

- a tile composing portion for reconstructing, from wavelet coefficients inputted from the wavelet coding portion, separate tiles each being composed of $N \times M$ wavelet coefficients forming a (membership) set to be separately entropy coded;

- a management information generating portion for generating management information necessary for independently decoding coded data outputted from the wavelet coding portion on a tile-by-tile basis as well as on a subband-by-subband basis; and

- a coded data integrating portion for composing a sequence of the coded data according to the management information from the management information generating portion and attaching the management information to the coded data.

[0042]

Another object of the present invention according to the claim 6 is to provide an image coding device having means as defined in any of claims 1 to 4, wherein the wavelet coding portion is provided with a memory necessary for storing at least data for the tile.

[0043]

Another object of the present invention according to the claim 7 is to provide an image coding device having means as defined in any of claims 1 to 6, wherein the wavelet-coding portion performs multiple times the subband decomposition process by selectively applying suitable filters for respective subbands.

[0044]

Another object of the present invention according to the claim 8 is to provide an image coding device having a combination of plural coding systems selectable from claims 1 to 7 and having a plurality of selectively applicable coding modes, which further includes a flag generating portion for generating flags indicating respective coding modes, a control portion for controlling the coding device in a mode specified by the flag generated by the flag generating portion, and a management information generating portion for generating management information from the flags outputted by the flag generating portion and tile-and-subband information.

[0045]

Another object of the present invention according to the claim 9 is to provide an image coding device having means as defined in any of Claims 1 to 8, which is further provided with an ID generating portion for generating IDs for identifying respective tiles and a management information preparing portion for preparing management information from IDs generated by the ID generating portion and tile-and-subband information outputted by the wavelet-coding portion.

[0046]

Another object of the present invention according to the claim 10 is to provide an image coding device having means as defined in claim 9, which is further provided with a peripheral tile ID deciding portion for generating IDs of peripheral tiles around an objective tile to be coded by using ID information from the ID generating portion and tile information from the wavelet coding portion, and a management information preparing portion for preparing management information from IDs of an ID of the objective tile, IDs of peripheral tiles and tile-and-subband information from the wavelet coding portion.

[0047]

Another object of the present invention according to the claim 11 is to provide an image decoding device for receiving coded data coded and inputted by the image coding device of claim 1 and reproducing a desired image by selectively decoding the coded data of necessary tiles and subbands, comprising:
a management information separating portion for separating

tile-and-subband management information from input coded data;

a coded data extracting portion for selectively extracting coded data of required decodable objective tiles and subbands according to the management information;

a wavelet decoding portion for performing wavelet decoding of the extracted coded data in compliance with the wavelet coding conducted by the image coding device of claim 1; and

a tile combining portion for combining wavelet-decoded tile images into a desirable image.

[0048]

Another object of the present invention according to the claim 12 is to provide an image decoding device for receiving coded data coded and transmitted by the image coding device of claim 2 and reproducing a desired image by selectively decoding the coded data of necessary tiles and subbands, comprising:

a management information separating portion for separating tile-and subband management information from the input coded data;

a coded data extracting portion for extracting coded data part corresponding to an objective tile and subbands according to the management information;

a wavelet decoding portion for performing wavelet decoding of the extracted coded data in compliance with the wavelet coding conducted by the image coding device of claim 2; and

a tile integrating portion for arranging wavelet decoded data at respective places on an original image and superposing image values at overlaps of neighboring tiles to integrate the tiles into a desired decoded image.

[0049]

Another object of the present invention according to the claim 13 is to provide An image decoding device for receiving coded data coded and inputted by the image coding device defined in any of claims 3 to 5 and reproducing a desired image by decoding the coded data of necessary tiles and subbands, comprising:

a management information separating portion for separating tile-and subband management information from the input coded data;

a coded data extracting portion for extracting coded data part corresponding to an objective tile and subbands according to the management information;

a wavelet decoding portion for performing wavelet decoding of the extracted coded data in compliance with the wavelet coding conducted by the image coding device defined in any of claims 3 to 5; and

a tile integrating portion for arranging wavelet-decoded data at respective places on an original image and superposing image values at overlaps of neighboring tables to integrate the tiles into a desired decoded image.

[0050]

Another object of the present invention according to the claim 14 is to provide an image decoding device for receiving coded data coded and inputted by the image coding device defined in any of claims 3 to 5 and reproducing a desired image by selectively decoding the coded data of necessary tiles and subbands, comprising:

a management information separating portion for separating tile-and subband management information from input coded data;

a coded data extracting portion for selectively extracting coded data of required decodable objective tiles and subbands according to the management information;

a wavelet decoding portion for performing wavelet decoding of the extracted coded data in compliance with the wavelet coding conducted by the image coding device defined in any of claims 3 to 5, and

a wavelet-coefficient rearranging portion for rearranging the wavelet coefficients reconstructed on a tile-by-tile basis by the wavelet decoding portion into an initial order of them before having been tiled.

[0051]

Another object of the present invention according to the claim 15 is to provide an image decoding device having means as defined in any of claims 11 to 14, wherein the wavelet decoding portion includes a memory for storing data at least for the tile.

[0052]

Another object of the present invention according to the claim 16 is to provide an image decoding device having means as defined in any of claims 11 to 15, wherein the wavelet decoding portion repeats multiple times the subband composition with use of filters changeable for respective subbands.

[0053]

Another object of the present invention according to the claim 17 is to provide an image decoding device for receiving coded data encoded and inputted by the image coding device defined in claim 8, the device having a combination of plural decoding systems selectable from claims 11 to 16 with plural decoding modes and selectively decoding coded data for necessary tiles and applicable, wherein it is further provided with:

- a management information separating portion for separating management information from the input coded data;

- a flag extracting portion for extracting from the management information a flag for specifying a decoding mode used for decoding the coded data; and

- a control portion for controlling the decoding device to be activated in a decoding mode corresponding to the extracted flag.

[0054]

Another object of the present invention according to the claim 18 is to provide an image decoding device as defined in

any of claims 11 to 17, which receives coded data encoded and inputted by the image coding device defined in claim 9 and reproduces a desirable image by decoding the coded data on the subband-by-subband basis and on the tile-by-tile basis, wherein it is further provided with an objective tile deciding portion for deciding an ID of a tile to be decoded and a control portion for controlling input data to the wavelet decoding portion according to management information from the management information separating portion so as to decode only decoded data of the tile having the decided ID.

[0055]

Another object of the present invention according to the claim 19 is to provide an image decoding device as defined in claim 18, which receives coded data encoded and inputted by the image coding device of claim 10 and reproduces a desirable image by selectively decoding the coded data on the subband-by-subband basis and the tile-by-tile basis, wherein it is further provided with a buffer for storing input coded data and a control portion that recognizes next coded data to be decoded being a tile decided by the objective tile decided portion by referring to the management information separated by the management information separating portion and controls the buffer so that only coded data for the decided tile and peripheral tiles specified by the management information is inputted to the wavelet decoding portion.

[0056]

Modes for carrying out the present invention is described to the details in the followings. Figure 1 is a block diagram of an image coding device according to an embodiment 1 of the present invention.

[0057]

Image data of an original image as shown in Fig. 2(a) is decomposed by a tile decomposition portion 101 into tiles each of predetermined N pixels by M pixels. The decomposed image is shown in Fig. 2(b). The tile decomposition portion 101 outputs N pixels by M pixels image in a tile as corresponding data to each tile.

[0058]

Further processing will be described by way of example on a tile "1" in Fig. 2(b). Image data of the tile "1" is divided by a wavelet transform portion 102 into subbands.

[0059]

Data at the periphery of a tile is extrapolated when dividing the tile portion near its boundary into subbands. For example, as shown in Fig. 37(b), an area 3702 covered by a wavelet transform filter exists out of a tile. In this case, it is needed to add data at the periphery of the tile. The wavelet transform portion 102 therefore extrapolates data at the periphery of each tile and divides the tile into subbands.

[0060]

The data extrapolation is achieved for example by generating a mirror image by outwardly folding an internal

image of the tile as shown in Fig. 2(c). A quantizing portion 103 quantizes wavelet transform coefficients and an entropy coding portion 104 performs entropy coding of the coefficients to obtain coded data of the tile "1".

[0061]

The entropy coding can be achieved by using a known Huffman coding method or arithmetic coding method. The wavelet transform portion 102, quantizing portion 103 and entropy coding portion 104 composes a so-called wavelet transform coding portion 105.

[0062]

On the other hand, a management information generating portion 106 generates information for identifying and managing tiles and subbands by using information on spatial locations of each tile from the tile decomposition portion 101 and information on each subband from the wavelet transform coding portion 105. The management information is utilized by a coded data integration portion 107.

[0063]

Using the management information from a management information generating portion 106, the coded data integration portion 107 arranges and integrates information on the coded data from the entropy coding portion 104 and adds the management information to a bit stream to generate coded data.

[0064]

Management of the coded data according the tiles and

subbands is needed for achieving decoding of a coded image at different resolution levels as shown in Fig. 32(a) or a particular tile or tiles of the coded image.

[0065]

Figure 3 shows an example of a bit stream of coded data produced in the above-described manner. The bit stream is composed of a header for managing information on a whole bit stream and information on each tile. Information for each tile consists of a tile header for managing the tile information and coded information representing a tile image encoded by the wavelet transform coding portion 105.

[0066]

The tile header includes information on bit positions corresponding to respective subbands. A bit sequence corresponding to necessary one of the subbands can be found by accessing this information.

[0067]

The structure of bit streams used in the system of the present invention is not limited to that shown in Fig. 3. For example, a sequence of Fig. 4(a) is similar to the sequence of Fig. 3, while a sequence of Fig. 4(b) has the form in which each subband for a tile is separated and rearranged with a tile header added thereto. The latter sequence allows the system to quickly reproduce a desirable contracted image by accessing only necessary tile or tiles in the sequence.

[0068]

An image coding device according another embodiment 2 of the present invention will be described as follows. The image coding device of the embodiment 2 is similar in construction to the embodiment 1 shown in Fig. 1 but differs from the embodiment 1 described above with the figure 8 by the operation of the tile decomposition portion 101, which will be described below with reference to Fig. 5.

[0069]

While the tile decomposition portion 101 of the embodiment 1 decomposes an image into tiles each of N pixels by M pixels and outputs only image data within each tile to the wavelet transform portion 102, the tile decomposition portion 101 of embodiment 2 outputs image data obtained by multiplying the original image by a suitable window function.

[0070]

For example, in case of extracting a tile "ij", the output of the tile decomposition portion 101 is a result of multiplying the original image data by a window function F_{X_i} in the horizontal direction and by a window function F_{Y_j} in the vertical direction. i denotes a horizontal tile number and j denotes a vertical tile number.

[0071]

This means that the output of the tile decomposition portion 101 represents a weighted result of multiplying a shaded image portion (Fig. 5) by a weight corresponding to window functions. Window functions are such that a total of

functions over a whole area is equal to 1. Window functions satisfying the following conditions are used.

[0072]

$$\sum FX_i(x)=1 \quad (0 \leq x \leq w)$$

$$\sum FY_j(y)=1 \quad (0 \leq y \leq h)$$

[0073]

where, w is the width of the original image, h is the height of the original image, x and y are the axes of abscissa and ordinate, respectively, with the origin at the top right corner of the original image.

[0074]

A total of the functions $FX_i(x)$ is taken for i and $FY_j(y)$ is taken for j . In Fig. 5, FX_{i-1} , FX_i , FXY_i , FY_j , FY_{j+1} are exemplary functions satisfying the above conditions.

[0075]

In consequence of the extraction of data by applying window functions, the output of the tile decomposition portion 101 includes pixels of a tile ij plus peripheral pixels weighted with the window function values.

[0076]

An image decoding device for decoding coded data from the image coding device of the embodiment 1 will be now described as an embodiment 3 of the present invention. Figure 6 is a block diagram of the image decoding device according to the embodiment 3.

[0077]

The image decoding device receives coded data from the image coding device described as the embodiment 1 of the present invention. A management data separating portion 401 takes out information for managing tiles and subbands from the received coded data.

[0078]

A coded data extracting portion 402 selectively extracts coded data of necessary tile and subbands according to the user's request. In the exemplary bit stream shown in Fig. 10, the management information is found in the header and the tile header.

[0079]

The extracted coded information is entropy-decoded by an entropy decoding portion 403 and inversely quantized by an inverse quantizing portion 404 to produce wavelet-transform coefficients corresponding to the tile to be decoded.

[0080]

The wavelet-transform coefficients are inversely transformed by an inverse wavelet transform portion 405 to produce a decoded image of the objective tile. The entropy-decoding portion 403, inverse quantizing portion 404 and inverse wavelet-transform portion 405 compose a so-called wavelet-transform decoding portion 406.

[0081]

A tile combining portion 407 combines together decoded tiles according to the tile managing information from the

management information generating portion 401 to generate a decoded image of the desired area or at a desired resolution.

[0082]

The decoding process with the bit stream shown in Fig. 3 is as follows. To decode a low-resolution entire image (all tiles), coded data (1-a, 2-a, ..., i-a, ...), which correspond to low-resolution subbands, are decoded in order in respective tile by the wavelet-transform decoding portion 116 according to the tile with referring to subband information included in each tile header.

[0083]

The low-resolution decoded tiles are then combined by the tile-combining portion 407, thereby a whole low-resolution image is reproduced.

[0084]

From the low-resolution decoded image, a particular tile "i" can also be reproduced in an enlarged scale with the highest resolution by decoding all the coded information of the i-th tile which correspond to the tile image "i".

[0085]

Namely, coded information i-b extracted and decoded together with already extracted coded information i-a to obtain the desired decoded image. It is, of-course, possible to reproduce a high-resolution decoded image of all areas by decoding all coded information (all tiles including all subbands).

[0086]

Thus, the image decoding device can easily decode any resolution image and/or any tile (partial) image can be easily decoded according to the user's request.

[0087]

An image decoding device according to another embodiment 4 of the present invention corresponding to the claim 12 is as follows:

Coded data is input from the image coding device according to the embodiment 2 of the present invention. This image decoding device is similar in construction to the embodiment 3 shown in Fig. 6 and differs from the latter by the operation of the tile-combining portion 407, which will be described below with reference to Fig. 7.

[0088]

In the image coding device according to the embodiment 2, pixels of each tile have been encoded together with pixels at its periphery. Therefore, data of a tile decoded in a wavelet-transform decoding portion 406 of this image decoding device is larger than an actual tile.

[0089]

In Fig. 7, a tile is composed of 2×2 pixels and the data size of a decoded tile is of 4×4 pixels. In this case, decoded data of a tile ij has an area shaded in Fig. 7, which overlaps neighbors each by one pixel width.

[0090]

The tile-combining portion 407 determines a pixel value for each overlap by adding together decoded data thereat when linking the decoded tiles. For example, the value of a pixel "a" in Fig. 7 is calculated as follows:

$$a(i-1,j-1)+a(i,j-1)+a(i-1,j)+a(i,j)$$

[0091]

where $a(i,j)$ represents decoded data of the tile ij at the position of its pixel "a".

[0092]

An image coding device according to another embodiment 5 of the present invention will be described with reference to Fig. 8 showing its construction.

[0093]

This image coding device differs from the image coding device (embodiment 1) of Fig. 1 by the fact that it does not unconditionally conduct extrapolation of data at the periphery of an objective tile and utilizes another tile adjacent to the tile if such exists.

[0094]

Like the embodiment 1, this image coding device decomposes an original image into tiles as shown in Fig. 9(a) at its tile decomposition portion 501. The image coding device further processes a tile "i" of the image as follows: In a wavelet-transform coding portion 503, image data of the tile "i" is wavelet-transformed through a wavelet-transform filter. In this case, if the filter extrudes from the tile "i" into

neighboring tiles and covers part of pixels contained in the neighbors, image data of those pixels in the neighbors are also wavelet-transformed together with the image data of the objective tile "i" by the filter.

[0095]

Referring to Fig. 9, the objective tile "i" of Fig. 9(a) is extended by adding necessary shaded parts of neighboring tiles a-h as shown in Fig. 9(b) and then wavelet-transformed.

[0096]

An adjacent pixel adding portion 502 realizes the above process by recognizing neighboring tiles around the objective tile according to the tile decomposition information from the tile decomposition portion 501 and by adding necessary pixels if the neighbors exist.

[0097]

In the shown case, the adjacent pixel adding portion 502 adds to the objective tile "i" all neighboring pixels existing around there and outputs an increased volume of image data to a wavelet transform portion 503. The wavelet transform portion 503 must therefore transform a larger image area data as compared with the wavelet transform portion 102 of the embodiment 1 that transforms a single tile image.

[0098]

With an increased image data to be transformed, the image coding device requires an enlarged working area for processing the data, resulting in increasing the cost of the device and

decreasing the operating speed. Therefore, it is desirable to use another mode for reducing the size of data to be transformed by the wavelet-transform portion.

[0099]

This mode is such that the additional adjacent area to be added by the peripheral pixel adding portion 502 to an objective tile area is limited to one direction "x" or "y" as shown in Fig. 9(c) or 9(d) to reduce the image data to be input to the wavelet transform portion 503.

[0100]

For example, in case of Fig. 9(c), an objective tile is provided with necessary pixels from upper and lower neighboring tiles if they exist. The right and left sides of the objective tile are treated by generating mirror images by folding the inside image of the tile. The case of Fig. 9(d) differs the above case of Fig. 9(c) by adding pixels from the right and left neighbors and generating mirror images for its top and bottom sides.

[0101]

There are two alternative methods for performing the wavelet transform of the image data of the objective tile. One method is to recursively decompose any of the tile of Figs. 9(b), 9(c) and 9(d). The other method is to selectively apply any of the above three pixel-addition modes 9(b), 9(c) and 9(d) for each subband.

[0102]

The wavelet transform portion 503 generates wavelet transform coefficients of pixels included within the objective tile "i" using only for calculation purpose of wavelet transform coefficients of the pixels added thereto by the peripheral pixel adding portion 502.

[0103]

A quantizing portion 504 quantizes the wavelet transform coefficients and an entropy coding portion 505 performs entropy encoding of the quantized coefficients to obtain coded information of the objective tile "i". The wavelet transform portion 503, quantizing portion 504 and entropy-coding portion 505 composes a so-called wavelet transform coding portion 506.

[0104]

On the other hands, a management information generating portion 507 receives spatial-tile-position information from the tile decomposition portion 501 and subband information from the wavelet transform coding portion 506 and generates management information for managing and identifying tiles and subbands. The management information is used by a coded-data integrating portion 508.

[0105]

The coded data integrating portion 508 rearranges and integrates coded information outputted from the entropy coding portion 505 according to the management information outputted from the management portion 507 and then adds the management information to a bit stream to generate a final coded data as

shown for example in Fig. 3.

[0106]

An image coding device according to still another embodiment 6 of the present invention will be described below:

This image coding device is similar in construction to the device of the embodiment 5 described above with reference to Fig. 8 but differs from the latter only by the operation of its peripheral-pixel adding portion 502. The operation of the peripheral-pixel adding portion 502 is described below with reference to Fig. 10.

[0107]

An objective tile "i" in Fig. 10 is now processed by way of example as follows:

In the embodiment 5, the peripheral-pixel-adding portion 502 added to a tile "i" all pixels necessary for calculating wavelet-transform coefficients for pixels in the objective tile, that is, pixels in areas covered by a filter extending from the objective tile. The adjacent pixel areas are shown as shaded in Fig. 10.

[0108]

Since distant pixels have a small effect on wavelet transform coefficients in a tile "i", the embodiment 6 adds a result of multiplying peripheral pixels by a suitable weighing function to the tile "i" to reduce the number of pixels to be attached, i.e., lighten the computation work load.

[0109]

The weighting function is 1 for each pixel near the tile "i" and has a distance-dependent value approaching to zero as a distance from the tile "i" increases. In Fig. 10, there is an example of a weighting function. Pixels multiplied by the weighting function and actually added to the objective tile compose an effective pixel area mesh-dotted in Fig. 10. A peripheral pixel area shown as shaded only in Fig. 10 is necessary for wavelet transform calculation but is not added because its weighted value is zero.

[0110]

Alternatively, a stepwise weighting function may be applied, which is given 1 for each pixel within a specified distance from the tile "i" and 0 for all pixels existing over the specified distance.

[0111]

Another image coding device is described as an embodiment 7 of the present invention. Figure 11 is a block diagram of an image coding device according to the embodiment 7.

[0112]

This image coding device differs from the embodiment 1 of Fig. 1 and the embodiment 5 of fig. 5 by the fact that an original image is entirely wavelet-transformed by a wavelet transform portion 701 and, then, wavelet transform coefficients outputted from the wavelet transform portion 701 are rearranged per tile to compose respective tiles.

[0113]

In Fig. 11, an original image before tiling is wavelet-transformed by a wavelet transform portion 701. A tile composing portion 702 composes tiles by rearranging wavelet transform coefficients so that a tile is composed of coefficients spatially matching the same tile.

[0114]

Figure 12(a) shows an example of subbands obtained by wavelet transform portion 701. In the shown case, a coefficient b_0 in the lowest frequency subband spatially correlates with other subband coefficients b_1 , b_2 , b_3 , b_4 , b_5 , b_6 , b_7 , b_8 and b_9 .

[0115]

Where b_1 - b_3 consist each of 1×1 coefficient, b_4 - b_6 consist each of 2×2 coefficients and b_7 - b_9 consist each of 4×4 coefficients. These coefficients b_0 - b_9 are taken out of the respective subbands and then arranged to compose a single tile as shown in Fig. 12(b). Likewise, all other wavelet transform coefficients are arranged to compose respective tiles. This results in obtaining the same result as in the embodiment 5 whereby an original image is first decomposed into portion tiles and then wavelet transformed.

[0116]

b_0 is not necessarily a single coefficient, but it may be a block composed of $k \times 1$ coefficient.

In this case, b_1 - b_3 consist each of $k \times 1$, b_4 - b_6 consist each of $2k \times 2l$ and b_7 - b_9 consist each of $4k \times 4l$ coefficients.

[0117]

Wavelet transform coefficients organized per tile are outputted from the wavelet transform portion 702. They are quantized by a quantizing portion 703 and entropy-encoded by an entropy-coding portion 704, thus coded information is generated.

[0118]

On the other hand, a management-information generating portion 706 generates management information necessary for managing and identifying tiles and subbands using spatial-tile-location information from the tile composing portion 702 and subband-location information from the wavelet transform coding portion 705. The management information is used by a coded-information integrating portion 707.

[0119]

The coded information integrating portion 707 receives the management information from the management information generating portion 706 and the coded information from the entropy-coding portion 704 and it arranges and combines the entropy coded information and adds management information in a bit stream of the coded data, thus generating finally coded data as shown in Fig. 3.

[0120]

Although the tile-composing portion 702 is installed before the quantizing portion 703 in this embodiment, it is not limited to this arrangement and may be placed after the

quantizing portion 703.

[0121]

An image decoding device for decoding data encoded by any one of the above-described image coding devices (embodiment 5 to 7) is now described below as an embodiment 8 of the present invention. Figure 13 is a block diagram showing the construction of the image decoding device according to the embodiment 8. The decoding device receives coded data encoded by any one of the image coding devices described above as embodiments 5 to 7.

[0122]

Referring to Fig. 13, the image decoding device separately takes out tile-decomposition management information and subband-management information from the input coded-data stream by a management information separating portion 901 and selectively extracts a necessary part of the coded information meeting the user's demand by a coded data extracting portion 902 according to the management information. Namely, the coded data corresponding to a necessary objective tile(s) having a necessary resolution is extracted by the coded data extracting portion 902.

[0123]

The extracted coded information is entropy-decoded by an entropy decoding portion 903 and inversely quantized by an inverse quantizing portion 904. Thus, wavelet transform coefficients corresponding to an objective tile to be decoded

are now obtained.

[0124]

The wavelet transform coefficients inversely transformed by an inverse wavelet transform portion 905, thereby a decoded image including peripheral pixels data is produced. The entropy coding portion 903, the inverse quantizing portion 904 and the inverse wavelet transform portion 905 compose a so-called inverse wavelet transform decoding portion 906.

[0125]

A tile combining portion 907 integrates groups of the decoded tiles according to the management information from the management information-separating portion 901. In this case, a completely decoded image is reproduced with overlaps of decoded tile images at each spatially overlapped portion.

[0126]

Namely, the embodiment 2 described above with reference to Fig. 5 performed wavelet transform of each tile with adjacent pixels attached thereto. The embodiment 5 uses adjacent pixels in performing wavelet transform of each tile as shown in Fig. 9(b). Likewise, the embodiment 6 described with reference to Fig. 10 also uses peripheral pixels in wavelet transform of each tile.

[0127]

In the image coding device according to the embodiment 7, the process using adjacent pixels is not clearly described but the wavelet transform of a whole original image has been done

including the processing theoretically equivalent to that made in the embodiment 5.

[0128]

Therefore, data of peripheral pixels is produced when each tile image is decoded by the wavelet transform decoding portion 906 in Fig. 13 and the decoded adjacent pixels are superposed on respective neighboring tiles by the tile combining portion 907. The superposition of one pixel on another is achieved by additive operation on the pixels.

[0129]

Another image decoding device is described below as an embodiment 9 of the present invention. Like the above embodiment 8, the input to this embodiment 9 is coded data encoded by any one of the image coding devices being the embodiments 5 to 7. Figure 14 is a block diagram showing the construction of the image coding device according to the embodiment 9.

[0130]

Referring to Fig. 14, a management information separating portion 1001 separately takes out tile-division management information and subband management information from the input coded-data stream, and a coded data extracting portion 1002 selectively extracts a necessary part of the coded information meeting the user's demand according to the management information. Namely, the coded data corresponding to a necessary objective tile(s) having a necessary resolution is

extracted by the coded data extracted portion 1002.

[0131]

The extracted coded information is entropy-decoded for each tile by an entropy-decoding portion 1003 and inversely quantized by an inverse quantizing portion 1004. Wavelet transform coefficients corresponding to an objective tile to be decoded are thus obtained. A wavelet transform coefficient rearranging portion 1005 rearranges the wavelet transform coefficients into the state in which they were placed before tile-by-tile arrangement.

[0132]

Namely, the wavelet transform coefficients divided per tile as shown in Fig. 12(b) are rearranged in the state shown in Fig. 12(a). After completion of processing on all tiles, all wavelet transform coefficients of Fig. 12(a) are obtained.

[0133]

The rearranged wavelet transform-coefficients can be decoded at a time by inverse transformation. Namely, the coefficients are inversely transformed by an inverse wavelet transform portion 1006, thereby a whole decoded image is reproduced.

[0134]

The entropy coding portion 1003, the inverse quantizing portion 1004 and the inverse wavelet transform portion 1006 compose a so-called inverse wavelet transform decoding portion 1007. Although the wavelet transform coefficient rearranging

portion 1005 is installed after the inverse quantizing portion 1004 in this embodiment, it is not limited to this arrangement and may be placed before the inverse quantizing portion 1004.

[0135]

An image coding device is described below as an embodiment 10 of the present invention. Figure 15(e) is a block diagram of a portion of this embodiment, which responds to the wavelet transform portion (102 in Fig. 1, 503 in Fig. 8) of the image coding devices according to the embodiments 1, 2, 5 and 6.

[0136]

Referring to Fig. 15(e), a memory 1102 is used for storing wavelet transform coefficients divided into subbands by a wavelet transform portion 1101. In this case, the memory 1102 stores only wavelet transform coefficients corresponding to a tile being currently processed by the wavelet transform portion 1101. The processed data are transferred to a quantizing portion (103 in Fig. 1, 504 in Fig. 8) following the wavelet transform portion 1101.

[0137]

Therefore, the memory 1102 has no need to store all data for a whole image and is sufficient to store such an amount of data necessary for processing only one tile.

[0138]

Namely, if wavelet-transformation without tile decomposition is applied to a whole image as shown in Fig. 15(a), it is necessary to store all wavelet transform coefficients

(Fig. 15(b)) outputted from the wavelet transform portion 1101. In contrast to the above, the decomposition of an image into tiles as shown in Fig. 15(c) enables the coding device to use a memory for storing only wavelet transform coefficients corresponding to a small image of Fig. 15(d), thus realizing a considerable saving of the memory capacity.

[0139]

The same effect can be realized in an image decoding device. An image decoding device is described below as another embodiment 11 of the present invention. Figure 16(e) is a block diagram, which corresponds to the inverse wavelet transform portion (405 in Fig. 6, 905 in Fig. 13) of the image decoding devices described before as the embodiments 3, 4 and 8.

[0140]

Referring to Fig. 16(e), a memory 1201 stores wavelet transform coefficients necessary for decoding one tile and an inverse wavelet transform portion 1202 performs the composition of subbands.

[0141]

An image that must be decoded is assumed to be that shown in Fig. 16(b). When performing the wavelet transform of the image without decomposition into tiles, it is necessary to store all wavelet transform coefficients as shown in Fig. 16(a). On the contrary, when decoding an image decomposed into tiles as shown in Fig. 16(d), the image decoding device can operate using a memory 1201 storing the limited number of wavelet

transform coefficients as shown in Fig. 16(c). The necessary memory capacity can be considerably saved.

[0142]

All the above-described embodiments can be provided with a plurality of subband-decomposition filters that are adaptively switched over one another to use in the process of wavelet transform coding (claim 7).

[0143]

The subband decomposition filters mean low-pass filters and high-pass filters for decomposing an image into subbands as described before for the prior art devices. The subband decomposition process is iterated for wavelet transformation. Filters to be used for this purpose are of various types having different numbers of taps and different coefficient values.

[0144]

Accordingly, it is desirable to selectively apply suitable one of filters to each subband-decomposition because this enables the coding device to change a necessary amount of adjacent pixels for an objective image by applying a suitable filter for a current subband. Optimal wavelet transformation of an image may be achieved by finding a reasonable compromise between the processing data amount and the image quality.

[0145]

In image decoding devices responding to such image coding devices, each subband composition filters responding to respective subband decomposition filters used for wavelet

transformation are selectively used for each of subbands to be combined through inverse wavelet transformation.

[0146]

An image coding device is described below as another embodiment 12 of the present invention. In the embodiment 12, an input image can be encoded by one of plural predetermined coding methods.

[0147]

Figure 17 is a block diagram showing an exemplary image coding device according to the embodiment 12. This embodiment 12 performs the image coding by switching the coding mode from the method of the embodiment 1 to the method of the embodiment 7 or vice versa.

[0148]

Referring to Fig. 17, a tile wavelet-coding portion 1601 performs wavelet encoding of the input image on a tile-by-tile basis and outputs coded information. This tile wavelet coding portion 1601 also outputs tile decomposition information, subband information and flag information.

[0149]

A tile-management-information generating portion 1603 receives the tile-decomposition information, the subband information and the flag information, and it prepares and provides management information including a combination of the above inputs. A coded data integration portion 107 outputs encoded data which combine the coded information and the

management information.

[0150]

In the tile wavelet coding portion 1601, an input original image is decomposed into tiles by the tile decomposition portion 101 and the decomposed image (tiles) is input to a terminal 0 of a first switch 1604. The input original image is input to a terminal 1 of the first switch 1604. Either of two images through the switch 1604 is input to a wavelet transform coding portion 1607.

[0151]

The wavelet transform coding portion 1607 performs wavelet encoding of the input image. The output of a first wavelet transform portion 1608 is input to a quantizing portion 103 through a second switch 1605 or to the quantizing portion 103 through a tile-composing portion 702.

[0152]

The operation of the first wavelet transform portion 1608 is similar to the wavelet transform portion 102 of the embodiment 1 described with reference to Fig. 1. So, the portion is not further described.

[0153]

A flag generating portion 1602 outputs a flag for selecting the encoding method of the embodiment 1 or the encoding method of the embodiment 7 and, at the same time, controls the first switch 1604, second switch 1605 and third switch 1606.

[0154]

When the switches 1604, 1605, 1606 are connected to terminals 0, the coding device performs the coding operation in the same way as the embodiment 1 does. With the switches connected to terminals 1, the coding device conducts the coding operation in the same way as the embodiment 7 does.

[0155]

The operation of a tile-composing portion 702 is the same as that of the embodiment 7 described before with reference to Fig. 11. Further description is omitted.

[0156]

As described above, the present embodiment can encode an input image on a tile-by-tile basis and selectively switches the coding system to the method of the embodiment 1 featured by simple image-by-image processing or the method of the embodiment 7 featured by coding of each tile with no distortion at the boundary thereof.

[0157]

Figure 18 is a block diagram of another exemplary image coding device according to the embodiment 12. In this coding device, coding can be conducted by selectively applying the method of the embodiment 1 and the method of the embodiment 5.

[0158]

Referring to Fig. 18, the image coding device differs from the former type by omitting the tile composing portion 702 (Fig. 17) relating to the embodiment 7 and adding an adjacent pixel

adding portion 502 relating to the embodiment 5 and a second wavelet transform portion 1705 with a selector switch. Since the operation of the components of this coding device except tile wavelet-transform coding portions 1701 and 1702 (Fig. 18) are similar to those of the image coding device of Fig. 17, so further description is omitted.

[0159]

The wavelet transform coding portion 1702 performs wavelet coding of an input image and outputs coded information. This device has two inputs: one is connected to a first wavelet transforming portion 1608 and the other is connected to a second wavelet transforming portion 1705.

[0160]

When an image is input to the first wavelet transform coding portion 1608, the wavelet transform coding portion 1702 performs the same operation as the wavelet transform coding portion 1607. When an image is input to the second wavelet transform portion 1705, the wavelet transform coding portion 1702 performs the same operation as the wavelet transform coding portion 506, since the operation of the first wavelet transform portion 1705 is similar to that of the wavelet transform portion 503.

[0161]

In tile wavelet coding portion 1701, the input image is decomposed into tiles and transferred to a first switch 1703. On the other hand, the decomposed tile images with adjacent

pixels are inputted to a second switch 1704. A flag-generating portion 1706 selects the use of the first wavelet-transform portion 1608 or the second wavelet-transform portion 1705 in the wavelet transform coding portion and outputs a flag indicating the selection made.

[0162]

At the same time, the above selection causes the first switch 1703 or the second switch 1704 to turn ON. Once the first switch was turned ON, the decomposed image is inputted to the first wavelet transform portion 1608 whereby the same coding process as made in the embodiment 1 is performed. Once the second switch 1704 was selected, the image decomposed into tiles with peripheral pixels is inputted to the second wavelet-transform portion 1705 whereby the coding process of the embodiment 5 is performed.

[0163]

Thus, the image coding device can process an input image on a tile-by-tile basis and can encode the image by selectively applying the simple coding method of the embodiment 1 or the tile-boundary distortionless coding method of the embodiment 5, (by which each tile can be encoded without distortion of its boundary.

[0164]

Another exemplary image coding device according to the embodiment 12 is shown in Fig. 19, which is capable of selectively applying three different coding modes: methods of

the embodiments 1, 5 and 7.

[0165]

As shown in Fig. 19, this image coding device differs in construction from the image coding device of Fig. 18 by including a tile composing portion 702 and switching circuitry for realizing the coding mode of the embodiment 7. The operation of this device excepting a tile wavelet transform coding portion 1801 and a wavelet transform coding portion 1807 is similar to that of the device of Fig. 17, so further description of the portions is omitted.

[0166]

The wavelet transform coding portion 1807 performs wavelet encoding of an input image and outputs coded information of the image. The output of a first wavelet transform portion 1608 is inputted to a quantizing portion 103 through a third switch 1805 or further through a tile-composing portion 702. The output of a second wavelet-transform portion 1705 is inputted directly to the quantizing portion 103.

[0167]

In the tile wavelet-coding portion 1801, the input image is inputted directly to a terminal 0 of the first switch 1803. Alternatively, it is decomposed into tiles and then inputted to a terminal 1 of the first switch 1803, or it is decomposed into tiles each including necessary peripheral pixels and then inputted to a terminal 2 of the switch 1803.

[0168]

These images are transferred to a first wavelet-transforming portion 1808 or a second wavelet-transforming portion 1705 through the second switch 1804. The image data is quantized in a quantizing portion 103 and encoded in an entropy-coding portion 104 wherefrom coded information is outputted.

[0169]

A flag generating portion 1802 controls the first, second, third and fourth switches 1803, 1804, 1805, 1806 to selectively switch the coding modes 0, 1 and 2. The mode numbers are indicated at terminals of the switches 1803, 1804, 1805 and 1806 respectively.

[0170]

When the first switch 1803 is connected to the terminal 0, all remaining switches 1804, 1805 and 1806 are also connected to their terminals 0. With the switches 1803-1806 connected to the terminals 0, the image coding device encodes the input image by applying the coding mode of the embodiment 7.

[0171]

When the switches 1803-1806 are all connected to their terminals 1, the image coding device encodes the input image by applying the coding mode of the embodiment 1. When the first, second and fourth switches 1803, 1804, 1806 are connected to their terminal 2, the image coding device encodes the input image by using the coding mode of the embodiment 5.

[0172]

Thus, the image coding device can process an input image on a tile-by-tile basis and can also encode the image by selectively applying one of three coding modes: the simple tile-image-coding method of the embodiment 1, the tile-boundary distortionless coding method of the embodiment 5 or 7, (by which each tile can be encoded without distortion of its boundary).

[0173]

An image decoding device according to another embodiment 13 of the present invention is described below. The input to this device is coded data encoded by the image coding device according to the embodiment 12 of the present invention. The input data is decoded by this device by applying one of predetermined modes of decoding.

[0174]

Fig. 20 is a block diagram of an exemplary image decoding device according to the embodiment 13, which is capable of decoding coded data generated by the image decoding device (embodiment 13) by selectively applying two coding methods used in the embodiments 1 and 7.

[0175]

Referring to Fig. 20, coded information and management information are separated each other at a management-information separating portion 401 and inputted to a tile wavelet decoding portion 1901 that in turn performs tile-by-tile decoding of the coded data using the management

information and outputs a decoded image.

[0176]

The coded data is inputted to a wavelet transform decoding portion 1902 whereby it is wavelet-decoded. The image decoded by the wavelet transform decoding portion 1902 is outputted directly by a second switch 1904 or outputted through a tile-combining portion 407.

[0177]

In the wavelet transform decoding portion 1902, the output of an inverse quantizing portion 404 is applied to a first inverse wavelet-transform portion 1906 through a first switch 1903 or to the first inverse wavelet transform portion 1906 through a wavelet-coefficient rearranging portion 1005.

[0178]

The operation of the first inverse wavelet-transform portion 1906 is similar to that of the inverse wavelet-transforming portion 405 in the embodiment 3 (Fig. 6), so further description is omitted.

[0179]

A flag-generating portion 1905 extracts flags for controlling the first switch 1903 and the second switch 1904 from the management information. With the switches 1903 and 1904 connected to their terminals 0, the image decoding device performs the same decoding operation that the embodiment 3 does. With the switches 1903 and 1904 connected to the terminals 1, the image decoding device performs the same decoding operation

that the embodiment 9 does.

[0180]

The operation of a tile-combining portion 407 is similar to that of the same portion of the embodiment 3 described with reference to Fig. 6, so further description is omitted.

[0181]

The image decoding device according to the embodiment 13 can process coded image data on a tile-by-tile basis and can also decode the image by selectively applying two decoding modes: the simple tile-image-decoding method of the embodiment 3 and the tile-boundary distortionless decoding method of the embodiment 9, (by which each tile can be encoded without distortion of its boundary).

[0182]

Figure 21 is a block diagram of another exemplary image decoding device according to the embodiment 13 of the present invention, which is capable of decoding image data encoded by selectively applying two coding methods of the embodiments 1 and 5.

[0183]

The operation of this device except a tile wavelet transform decoding portion 2001 and a wavelet transform decoding portion 2002 (Fig. 21) are similar to that of the device of Fig. 20, so further description of the like portions is omitted.

[0184]

The wavelet transform decoding portion 2002 performs wavelet decoding of input coded information. The output of an inverse quantizing portion 404 through a first switch 2004 is inputted to a first inverse wavelet transform portion 1906 or a second inverse transforming portion 2003.

[0185]

The output of the first inverse wavelet transform portion 1906 is transferred to a tile composing portion 407 and the output of the second inverse wavelet transform portion 2003 is transferred to a tile integrating portion 907.

[0186]

The operation of the second inverse wavelet transforming portion 2003 is similar to the inverse wavelet transform portion 905 of the embodiment 8 described with reference to Fig. 13, so further description is omitted.

[0187]

In the tile wavelet decoding portion 2001, the wavelet transform decoding portion 2002 performs wavelet decoding of the coded information and outputs the decoded information to the tile composing portion 407 or the tile integrating portion 907. A decoded image is now reproduced.

[0188]

On the other hand, a flag-generating portion 2005 extracts a flag from the management information and controls the operation of a first switch 2004 by the extracted flag. With the switch 2004 connected to its terminal 0, the image decoding

device performs the same decoding operation that the embodiment 3 does. With the switch 2004 connected to its terminal 1, the image decoding device performs the same decoding operation that the embodiment 8 does.

[0189]

Thus, the image decoding device according to the embodiment 13 can process coded image data on a tile-by-tile basis and can also decode the image by selectively applying two decoding modes: the simple image-decoding method of the embodiment 3 and the tile-boundary distortionless decoding method of the embodiment 8, (by which each tile can be encoded without distortion of its boundary).

[0190]

Figure 22 is a block diagram of a further exemplary image decoding device according to the embodiment 13 of the present invention, which is capable of decoding image data encoded by selectively applying three coding methods of the embodiments 1, 5 and 7.

[0191]

Referring to Fig. 22, this image decoding device differs from the image decoding device of Fig. 21 by the provision of a wavelet-coefficient rearranging portion 1005 and related switch circuitry. Since the operation of this device excepting a tile wavelet transform decoding portion 2101 and a wavelet transform decoding portion 2102 (Fig. 22) is similar to that of the device of Fig. 20, so further description of the like

portions is omitted.

[0192]

The wavelet transform decoding portion 2102 performs wavelet decoding of input coded information. The output of an inverse quantizing portion 404 is inputted to a first inverse wavelet transform decoding portion 1906 through a terminal 0 of a first switch or a wavelet coefficient rearranging portion 1005 through a terminal 1 of the first switch 2103. Alternatively, it is transferred to a second inverse transforming portion 2103 through a terminal 2 of the first switch 2003.

[0193]

The output of the first inverse wavelet-transforming portion 1906 is transferred to a tile-composing portion 407 through a second switch 2104 or a decoded image is directly outputted. The output of the second inverse wavelet-transform portion 2003 is transferred to a tile-integrating portion 907. The operation of other components is similar to that of like components of the wavelet-decoding portion 2002, so further description is omitted.

[0194]

In the tile wavelet decoding portion 2101, a flag extracting portion 2105 extracts flags for controlling the first switch 2103 and the second switch 2104 from the management information. The remaining management information is inputted to the tile-composing portion 407 and the tile-integrating

portion 907.

[0195]

With the switches 2103 and 2104 connected to its terminal 0, the image decoding device performs the same decoding operation that the embodiment 3 does. With the switches 2103 and 2104 connected to its terminal 1, the image decoding device performs the same decoding operation that the embodiment 9 does. When the first switch 2103 is connected to its terminal 2, the device performs, the same decoding operation that the embodiment 8 does irrespective of the position of the second switch 2104.

[0196]

Thus, the image decoding device according to the embodiment 13 can process coded image data on a tile-by-tile basis and can also decode the image by selectively applying three decoding modes: the simple tile-image-decoding method of the embodiment 3 and the tile-boundary distortionless decoding method of the embodiments 8 and 9, (by which each tile can be encoded without distortion of its boundary).

[0197]

An image coding device is described below as an embodiment 14 of the present invention. In this embodiment, tile management information including information for identifying (distinguishing) tiles is utilized to realize high-speed decoding of any objective tile.

[0198]

Figure 23 is a block diagram showing an exemplary image coding device according to the embodiment 14. Referring to Fig. 23, a tile wavelet-coding portion 2201 performs wavelet encoding of an input original image on a tile-by-tile basis, and it generates coded information and management information such as tile-decomposition information, flag information and subband information.

[0199]

An ID generating portion 2202 generates ID information for identifying each tile. Management information generating portion 2203 generates management information by combining the management information with the ID information. A coded-data combining portion 2204 generates coded data by combining the coded information with the management information and placing a tile-information start code at the head of information of each tile.

[0200]

Figure 24(a) shows an example of the coded data format that defines each tile information consisting of a tile-information start code, management information (tile header) and coded data. The tile wavelet-coding portion 801 can be commonly used for image coding devices according to embodiments 1, 2, 5, 6, 7, 10, 12 and 14.

[0201]

To distinguish tiles into which an original image was decomposed, ID numbers (e.g., 1, 2, ...) are assigned to tiles

arranged in a sequence from the top left as shown Fig. 31. Tiles having ID numbers can be coded in any order and rearranged after coding. Moreover, the ID generating portion 2202 may be omitted if the order of tiles to be encoded is predetermined.

[0202]

The location of each tile can be found by its start code or by its data size (coded information plus tile header).

[0203]

Figure 25 is a block diagram of another exemplary image coding device according to the embodiment 14. This image coding device differs from the device of Fig. 23 only by the provision of a data-size calculating portion 2301, so the portions other than the calculating portion 2301 and the management-information generating portion 2302 are omitted from the scope of further description.

[0204]

Referring to Fig. 25, the data-size calculating portion 2301 calculates a size of coded data for each tile and outputs the calculation result. The management information generating portion 2302 prepares management information consisting of management information, ID information and a coded tile-data size.

[0205]

Figure 24(b) shows an example of a coded information format in which each tile, a coded tile-data size is placed at the head, and following other, management information (tile

header) and coded information. The coded tile-data size is not necessarily placed at the top of each tile field. Alternatively, data-size values for all tiles may be placed together at the top of the format.

[0206]

Figure 26 is a block diagram of another exemplary image coding device according to the embodiment 14. This image coding device differs from the device of Fig. 25 only by the provision of a coded-data rearranging portion 2401, so the portions other than the calculating portion 2401 and the management-information generating portion are omitted from the scope of further description.

[0207]

Referring to Fig. 26, the coded-data rearranging portion 2401 extracts a coded data size for each tile from coded data prepared by a code-data combining portion 2204 and puts the data-size value at the head of coded data and arranges other remaining data in a given order, then outputs a sequence of the coded data.

[0208]

In case of an exemplary coded-data format shown in Fig. 24(c), the location of any objective tile can be easily determined by summing data-size values from the top tile to a just preceding one.

[0209]

Figure 27 shows another exemplary image coding device

according the embodiment 14, which can realize the same effects as the above and which differs from the above device of Fig. 25 by the provision of a coded data storing portion 2501 and a management information storing portion 2502. Therefore, all components other than the coded data storing portion 2501, the management information storing portion 2502 and a coded data combining portion 2503 are omitted from further description.

[0210]

Referring to Fig. 27, coded information outputted from a tile wavelet coding portion 2201 are temporally stored in the coded data storing portion 2501. The management information storing portion 2502 stores tile management information generated by the management-information generating portion 2302. It extracts tile-size data from the tile-management-information, sends the data to the coded data combining portion 2503 and then outputs the remaining management information.

[0211]

First, the coded data-combining portion 2503 outputs all the data size values for all tiles and then outputs remaining management information combined with coded information.

[0212]

According to the embodiment 14 of the present invention, it is possible to immediately retrieve coded information of any desirable tile to be decoded.

[0213]

An image decoding device is described below as another embodiment 15 of the present invention. Figure 28 is a block diagram of an image decoding device according to the embodiment 15, which is capable of decoding coded data encoded and supplied by the image coding device according to the embodiment 14.

[0214]

Referring to Fig. 28, an objective-tile deciding portion 2603 decides an ID of an objective tile to be decoded according to the user's request. A management-information separating portion 2606 retrieves a start code indicating the head of the objective-tile coded information in a coded-data sequence and separates the objective tile management information from the objective-tile coded-information.

[0215]

Based on the management information, a data skip control portion 2602 decides whether the ID of the tile to be decoded matches the ID decided by the deciding portion. If two IDs match each other, the portion 2602 turns on both a first switch 2605 and a second switch 2604. Consequently, a tile wavelet-decoding portion 2601 can decode the selected tile only.

[0216]

If the tile management information includes each tile-data size, the management-information separating portion 2606 has no need to search tile-data heads and can find the location of the objective tile data head by skipping the unnecessary amount. The tile wavelet-decoding portion 2601 can be commonly

used in the image decoding devices according to the embodiments 3, 4, 8, 9, 11, 13 and 15.

[0217]

According to the embodiment 15, it is possible to immediately retrieve and decode the coded data of the object tile by using only the tile head management information without decoding any other coded data.

[0218]

An image coding device is now described below as another embodiment 16 of the present invention, which can provide coded tile images that can be decoded immediately to reproduce a single objective tile image as well as adjacent tile images by using tile-management information including neighbors' information.

[0219]

Figure 29(a) is a block diagram of an exemplary image coding device according to the embodiment 16. This device differs from the embodiment 14 of Fig. 23 by the addition of an adjacent tile ID deciding portion 2801 and by the operation of a management-information generating portion 2802. Other portions are similar to those of the embodiment 14 and omitted from the scope of further description.

[0220]

A tile wavelet-coding portion 2801 can be commonly used in the image coding devices of the embodiments 5, 6, 7, 10, 12 and 14.

[0221]

Referring to Fig. 29(a), the adjacent tile ID deciding portion 2801 decides IDs of adjacent tiles necessary for decoding an objective tile according to tile decomposition information, flag information, subband information and tile IDs produced by an ID generating portion 2202. A management-information generating portion 2802 prepares management information containing tile decomposition information, flag information, subband information and tile ID with adjacent tiles IDs.

[0222]

Since all adjacent tiles necessary for coding an objective tile are not necessarily given IDs, the number of adjacent IDs to be produced by the peripheral tile ID deciding portion 2801 may be limited to, for example, two neighbors existing left above and left below the objective tile as shown in Fig. 29(b).

[0223]

In the coded data format of Fig. 24(a), the management information (tile header) may include an objective tile ID and adjacent tiles' IDs.

[0224]

Figure 30 is a block diagram of an exemplary image coding device according to the embodiment 16 of the present invention, which is intended to encode tile images that may be rapidly retrieved for decoding by using management information including each objective tile ID with neighbors' IDs. This

image coding device is similar in construction to embodiment 14 of Fig. 27 but differs from the embodiment 14 by the absence of the management information storing portion 2502 and by the presence of a data-size storing portion 2901, relative position calculating portion 2902 and information storing buffer 2904.

[0225]

The operation of this image coding device is similar to the embodiment 14 except the operation with the data-size storing portion 2901, relative position calculating portion 2902, information storing buffer 2904, management information generating portion 2903 and ID generating portion 2905. Therefore, like components are not described further.

[0226]

Referring to Fig. 30, coded information outputted from a tile wavelet coding portion 2201 are all stored in a coded data storing buffer 2501. Tile-decomposition information, flag information and subband information from the tile wavelet coding portion 2201 are all stored in the information storing buffer 2904. Tile-data-size values outputted from the data-size calculating portion 2301 are all stored in the data-size storing portion 2901.

[0227]

The ID generating portion 2905 outputs ID information to identify each tile and controls the information storing buffer 2904, the data-size storing portion 2901 and the coded data storing buffer 2501 to output information on a tile-by-tile

basis. The data-size storing portion 2901 receives a tile ID and outputs a data-size value of the tile specified by the received ID to the management information generating portion 2903. It also provides the relative-position calculating portion 2902 with the tile-data-size necessary for calculating positions of neighbors relative to the tile having the ID.

[0228]

The relative-position calculating portion 2902 calculates the positions of coded information of the adjacent tiles relative to an objective tile by using the data-sizes of the input tiles and outputs the calculation results. The management information generating portion 2903 generates management information by using input information such as tile ID information, tile-decomposition information, flag information, subband information, tile-data-size values, relative positions of adjacent tiles, etc. It outputs the prepared management information to the coded data combining portion 2503.

[0229]

The above system can produce coded data of tile images, which can be effectively decoded at a high speed without decoding all coded data in such a way that coded data of an objective tile and necessary adjacent tiles may be retrieved and decode by decoding only management information located at the head of the decodable coded data.

[0230]

An image decoding device is described below as another embodiment 19 of the present invention. Figure 31 is a block diagram of the image decoding device according to the embodiment 19, which is used for decoding coded data produced by the image coding device according to the embodiment 18. This device is similar to and differs from the embodiment 15 of Fig. 28 only by the addition of a buffer 3001. All components other than the buffer 3001 and a skip-and-read control portion 3002 operate in the same way that like components of the embodiment 15. So, they are omitted from the scope of further description.

[0231]

Referring to Fig. 31 input coded data is temporally stored in the buffer 3001 wherefrom it is subsequently outputted later. The skip-and-read control portion 3002 extracts an ID for an objective tile according to the input management information. When the extracted ID matches the ID of the objective tile or the ID of a related adjacent tile, this control portion 3002 causes a first switch 2605 and a second switch 2604 to turn ON.

[0232]

If the management information contains IDs of adjacent tiles necessary for decoding the objective tile, the control portion 3002 controls the buffer storage 3001 to output the coded data of the adjacent tiles. Consequently, the tile wavelet-decoding portion 2601 can decode a specified tile and necessary neighbors.

[0233]

If the predetermined number (e.g., two dotted tiles in Fig. 29(b)) of peripheral IDs decoded in the management information is smaller than the number of necessary peripheral tiles (e.g., six unshaded neighbors in Fig. 29(b)), IDs of the remaining necessary neighbors are decided from the decoded IDs of the adjacent tiles.

[0234]

The tile wavelet-decoding portion 2601 can be commonly used in embodiments 8, 9, 11, 13 and 15.

[0235]

The above system can immediately decode any objective tile and necessary adjacent tiles by decoding only the management information put at the head of the coded data. It has no need of decoding all the coded data.

[0236]

[Effect of the Invention]

Accordingly, an object of the present invention is to provide an image coding and decoding system by which the image is effectively encoded and easily decoded with any resolution level desired by the user with no increase in volume of coded data.

[0237]

This is a great advantage of the present invention system as compared with the conventional Flash Pix system using the JPEG coding method, which has an increased amount to 1.4 times

of code data to provide a plurality of images having different resolutions.

[0238]

Another object of the present invention is to provide an image-coding and decoding system in which an image is decomposed into tiles and encoded on a tile-by-tile basis and the coded tiles can selectively decoded on the same principle by using the wavelet-transform coding/decoding technique. This could not be accomplished by the conventional wavelet-transform coding/decoding system because it is difficult in principle to apply the wavelet transform to closed tiles of the image.

[0239]

Another object of the present invention is to provide an image coding and decoding system that encodes an image on a tile-by-tile basis and allows the coded image to be partially decoded by selectively decoding only necessary tiles (without the necessity of decoding a whole image), thus improving the random access function of the system.

[0240]

In one aspect of the present invention, an image coding device as defined in the claim 1 can independently encode each of tiles of an original image, thus providing coded tile images that can be separately treated thereafter. If any of coded tiles must be further processed, it can be separately, processed and encoded again with no need of using adjacent pixels. Thus,

simple independent encoding and decoding of image tiles is realized.

[0241]

In another aspect of the present invention, an image decoding device as defined in the claim 11 can decode only a desirable coded tile image with no need of decoding any other coded data, thereby minimizing the processing load.

[0242]

In another aspect of the present invention, in spite of increasing of the coded-data size due to encoding an objective tile image including adjacent pixels by an image coding device as defined the claim 2 an image decoding device as defined the claim 12 decodes the coded tile image by superposing adjacent pixel values on overlaps, suppressing possible boundary distortion of the tile image.

[0243]

In still another aspect of the present invention, an image coding device as defined in any of the claims 3 to 5 and a corresponding image decoding device as defined in any of the claim 13 and 14 can encode tile images using pixel information on neighboring tiles, achieving high efficiency of image encoding using the correlation between tiles. This can also suppress possible boundary distortion of the tile images.

[0244]

In another aspect of the present invention, an image coding device as defined in the claim 3 can effectively encode a part

(plural tiles) of a whole image by performing wavelet transform of only selected tiles, and its wavelet transform is very compact.

An image decoding device responding to the above can also realize compact inverse wavelet transform of coded tile images.
[0245]

In a further aspect of the present invention, an image coding device as defined in the claim 4 can decide exclusion distant pixels from the scope of adjacent pixels for calculation. This minimizes the number of filtering operations and wavelet-transform operations.

[0246]

By using an image coding device as defined in the claim 5. A whole image is wavelet transformed at a time and then wavelet transformed coefficients are rearranged to compose respective tiles. This eliminates the need of iterating the wavelet-transform for each tile.

[0247]

In another aspect of the present invention, an image decoding device as defined in the claim 14 can rearrange coded data (decomposed for each tile) corresponding to an objective tile and then perform inverse wavelet transform of the coded data at a time, thus eliminating the need of repeating inverse wavelet transform for each tile.

[0248]

Conventional arts demand a large capacity of a memory for

holding wavelet transformed coefficients to correspond to resolution of an original image. In contrast to the above, an image coding device as defined in the claim 6 according to one aspect of the present invention can use, irrespective of the original image size, a memory which can store only wavelet transform coefficients for capacity corresponds to the size of a tile or tiles for a tile or tiles being currently encoded. This can realize a considerable saving of memory capacity needed.

[0249]

In another aspect of the present invention, an image decoding device as defined in the claim 15 can also use a memory having the capacity limited to a tile size for storing wavelet transform coefficients.

[0250]

In a further aspect of the present invention, an image coding device as defined in the claim 7 can conduct wavelet transform by selectively applying plural suitable filters for decomposing an objective tile image into subbands, thus realizing optimal wavelet transform of the objective tile with the best balance between the image quality and the processing load.

[0251]

In a further aspect of the present invention, an image decoding device as defined in the claim 16 can conduct inverse wavelet transform by selectively applying plural suitable

filters for composing subbands, which filters must respond to the subband decomposing filters. Thus, the device realizes the optimal inverse wavelet transform of each tile to be decoded.

[0252]

In a still further aspect of the present invention, an image coding device as defined in the claim 8 a corresponding image decoding device as defined in the claim 17 can selectively apply two wavelet transform modes: one for each tile with or without adjacent pixels and the other for each image with or without adjacent pixels. Two modes can be selected in accordance with the input image quality to minimize the increase of transform operations and deterioration of the image quality.

[0253]

In another aspect of the present invention, an image coding device as defined in the claim 9 a corresponding image decoding device as defined in the claim 18 can easily retrieve coded information of an objective tile to be decoded by searching management information well organized for identifying every tile. Therefore, it can realize high-speed retrieval and effective decoding of only plural tiles necessary for reproducing an area (several tiles) of a whole image.

[0254]

In still another aspect of the present invention, an image coding device as defined in the claim 10 a corresponding image decoding device as defined in the claim 19 can easily retrieve coded information of an objective tile and coded information

of adjacent tiles necessary for decoding the objective tile by using management information well organized for identifying every tile.

[0255]

Therefore, only an area (several tiles) of a whole image can be rapidly reproduced by decoding only necessary tiles.

High efficient coding/decoding of image tiles using adjacent pixel information is also achieved by utilizing the effect of correlative effect of the pixels.

[Document Name] Abstract

[Abstract]

[Object]

An image encoder/decoder by which a partial image is encoded easily with a resolution meeting the user's demand, the encoded amount of data is not increased and a necessary capacity of memory can be reduced.

[Solving Means]

The image encoder has a tile decomposition portion (101) which divides image data into tiles of N pixels x M pixels, a wavelet transform coding portion (105) which extrapolates predetermined data at the peripheries of the tiles outputted from the tile decomposition portion (101) and performs subdivision to perform wavelet encoding, a management information generating portion (106) which generates information for managing the encoded data in order that the encoded data outputted from the wavelet transform coding portion (105) can be decoded for each tile and for each subband of the wavelet encoding, and an coded data integration portion (107) which links the encoded data encoded by wavelet encoding for each tile by using the output of the management information generating portion (106) and adds the managing information to the encoded data.
